

ABSTRACT

When a service utilization terminal such as a mobile telephone accepts a user's input to execute an application, it utilizes a function required for the application via a connector specifying the function required for the application. In this case, the service utilization terminal requests a connector provision server for the connector and obtains it. Only a service utilization terminal holding the connector can access the service provision server described in the connector so that the function required for executing the application can be utilized with a high level of usability and a high level of safety.
